Software technical challenge

Congratulations on reaching this recruitment phase. We are looking forward to receiving your challenge results. Please find the challenge details below.

Challenge Description

One of Sensei's clients requested a web application that allows it to upload an image frame of one of the store's cameras and return it with a bounding box drawn around each person. This is useful, for instance, to verify if the store is empty at a certain point in time.

Your task is to develop the service that exposes a single HTTP endpoint that allows a user to upload an image and returns the same image but modified with bounding boxes around the detected people. The algorithm to detect people is out of the scope of your task, and you can use any library/framework found online. However, since this can be a computationally expensive operation if the user uploads the same image twice, we want to avoid running the detection algorithm more than one time. So consider this when developing the service.

Note: Sensei is a company that takes privacy very seriously, so it should never record any uploaded images on the service other than the duration of the request.

Guidelines

- You have one week to send in the result of your challenge.
- Make sure that your solution is fully executable.
- We recommend creating a Git repository to keep track of your code development.
- Send your implementation to acraveiro@sensei.tech and jspereira@sensei.tech (or share a private github repository with those accounts).
